# 1 Data Visualization and Observations (For extra marks)

## 1.1 Heat Map Visualisation

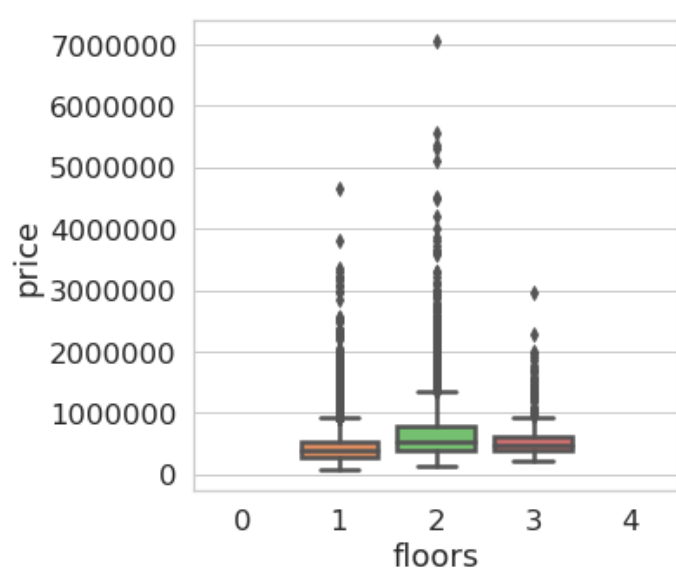

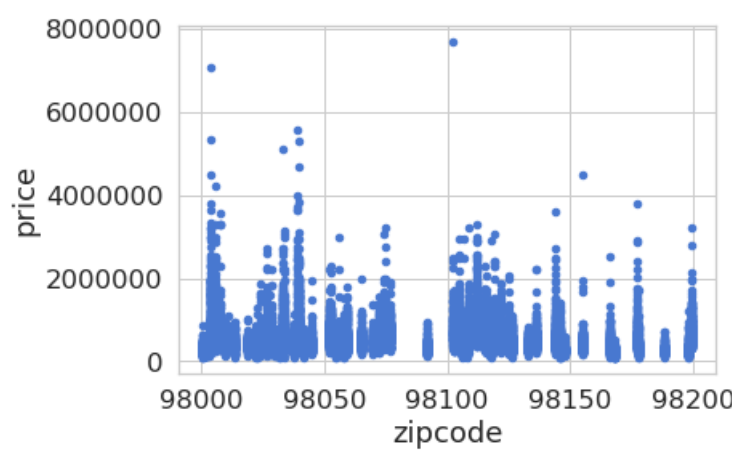

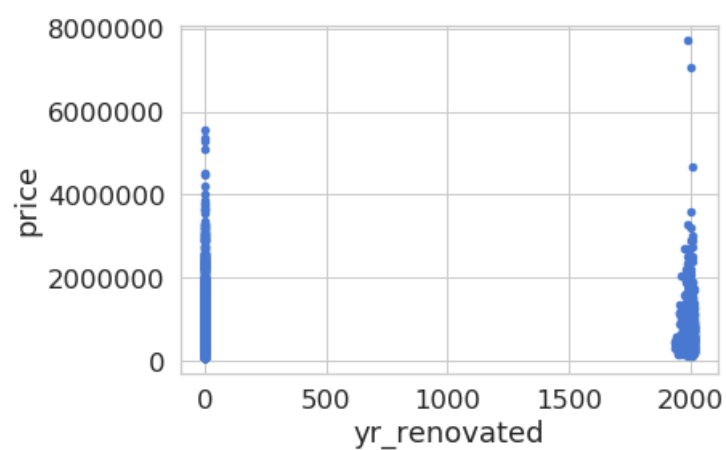

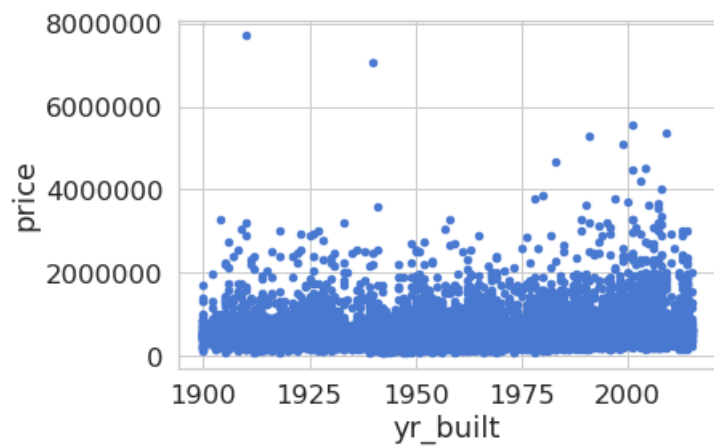

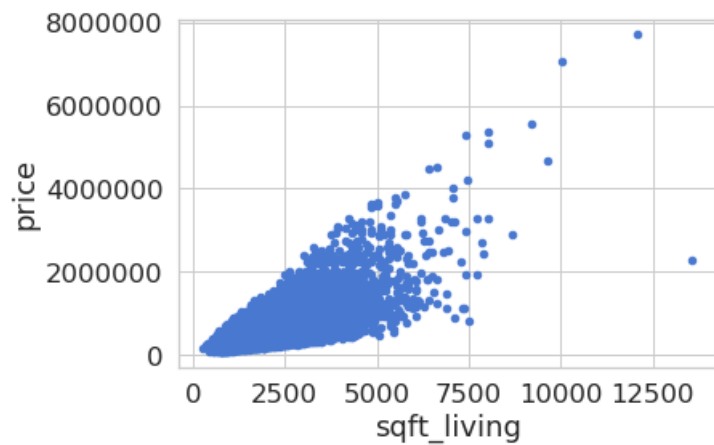

Figure 1: Heat Map

## 1.2 Box plot visualisation for categorical features

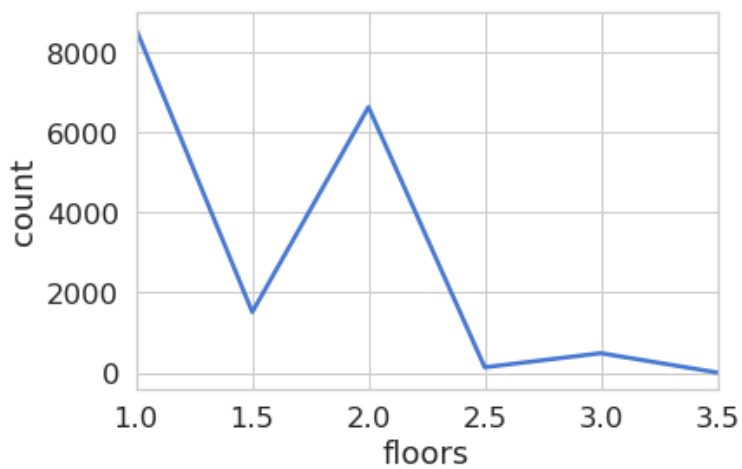

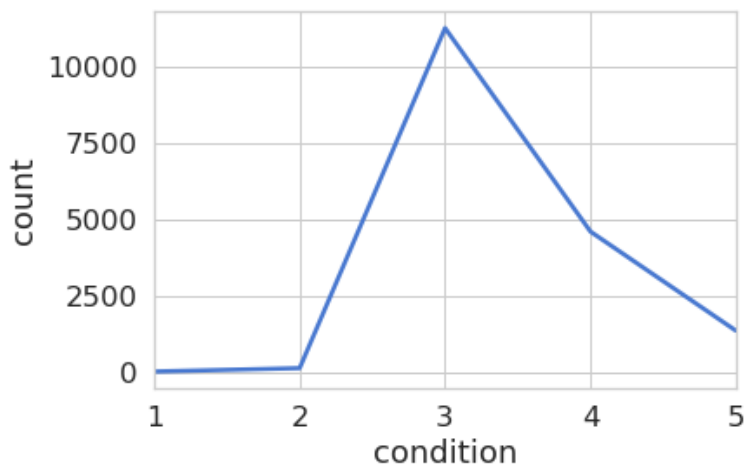

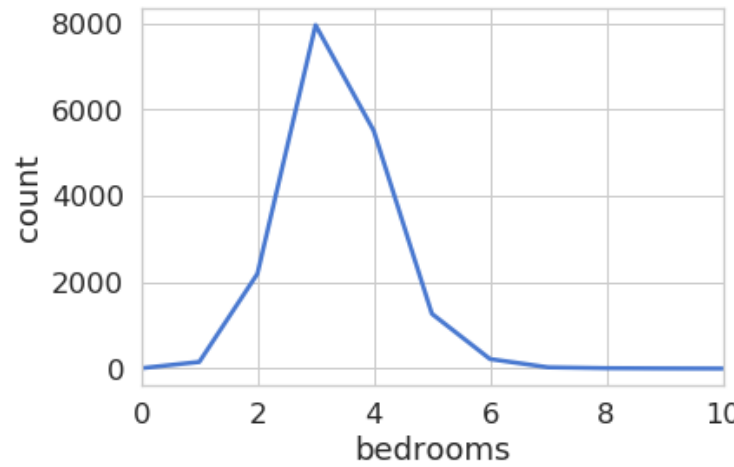

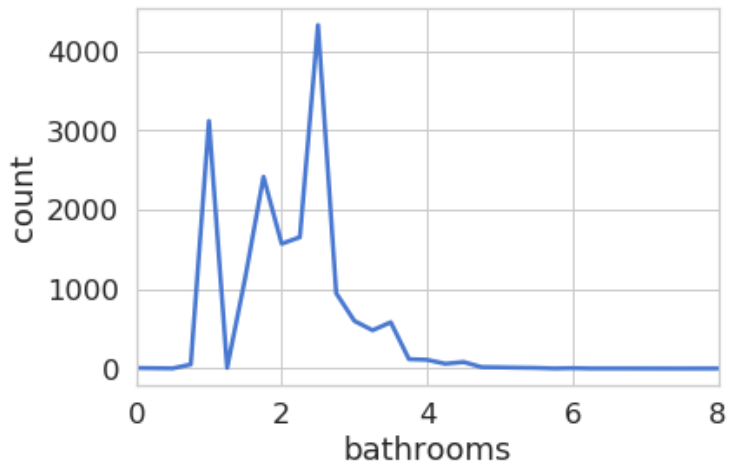

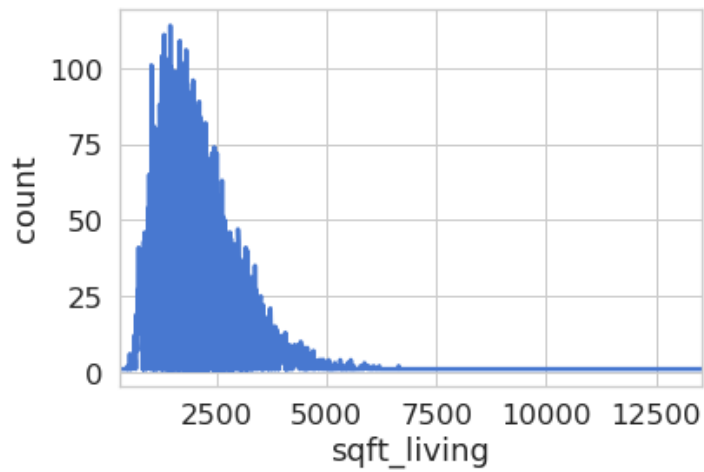

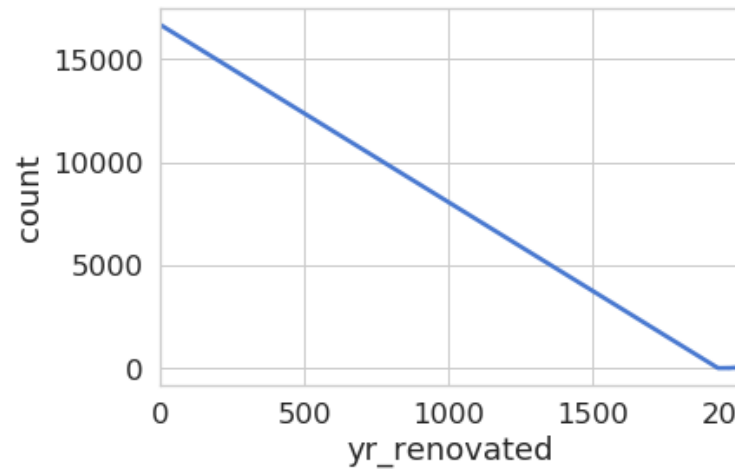

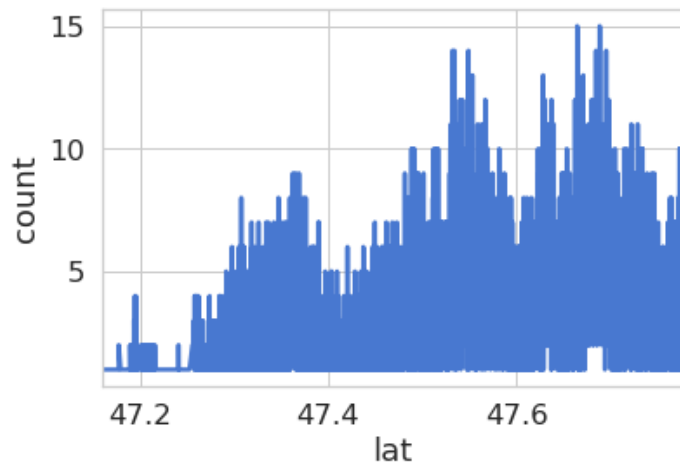

### 1.3 Scatter plot for continuous feature

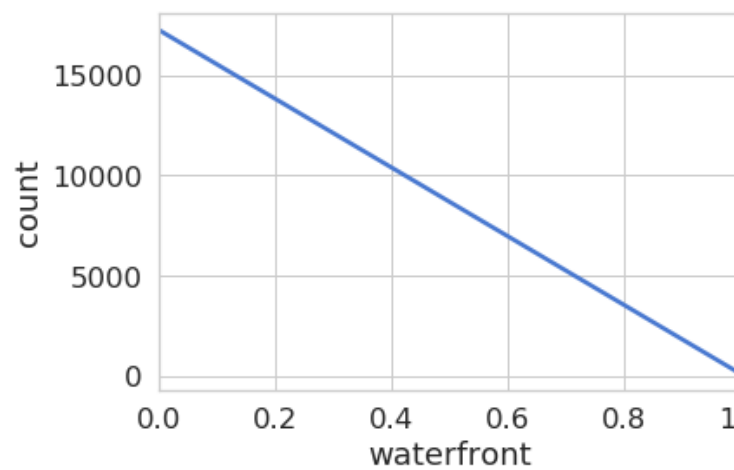

## 1.4 Distribution of features

## 1.5 TSNE plot

Figure 2: T-SNE Plot

## 1.6 KEY OBSERVATIONS

**Referring to heatmap:-**We have plotted here heatmap of correlation between all the pairs of feature(including price)

- As we can see here *sqft\_living* and *grade* shows good correlation with price. But both are

also correlated to each other so it would be better to drop one of them as they are redundant predictor.

- Date is least correlated to price. So, it can not be considered good feature for price prediction.
- Since bad feature selection may lead to bad result. So many algorithms have developed to tackle this.

**Referring to boxplot:-** We have plotted boxplot for categorical features. Here we have six categorical feature. For each of the feature we have plotted it against price.

- For grade and bathroom distribution shifts towards high price as the grade and bathroom increase which shows there is a relation between price and grade, price and bathrooms and can be used as feature for prediction.
- waterfront and bedrooms also show little amount of shift in distribution as the waterfront and bedrooms increases. which shows that higher the number of bedrooms and waterfront higher the price.

**Referring to scatter plot:-** For non-categorical features we have plotted scatter plot to check how individual feature is related to price.

- features like *lat*, *sqft\_above*, *sqft\_basement*, *sqft\_living*, *sqft\_living15* shows positive relation with price because as the feature value increases price also increase.
- features like *sqft\_lot*, *sqft\_lot15*, shows negative relation with price because as the feature value decreases price also decreases.
- features like *long*, *yr\_renovated*, *zipcode*, *date*, *yr\_built* does not show significant relation with price

**Referring to distribution plot:-** It shows how the feature is distributed. For example data points having 3 bathrooms are more in number in training set. Like wise for price we can see costlier house are very less in training set compared to cheap houses. Like this we can get idea of all features.

**Referring to T-sne plot:-** Here we have plotted the training data. We have run unsupervised clustering(t-sne) method on data. As we can see data is clustered or grouped. It shows that houses are divided in groups and each group will have some average price. For each group we can calculate average value for each feature. In this way we can also answer reverse query. Like some one ask-I have this much amount of money what type of house I can buy?, I have this much amount of money can I buy house with four bedrooms etc.

## 2 Polynomial Regression
